SDNL130 - Seismic response of a reinforced concrete beam (rectangular section) to nonlinear behavior

Summary:

The problem consists in analyzing the seismic answer of a reinforced concrete beam. Comportement of the beam $BA$ is nonlinear. Two modelings are studied:

- the beam is represented by a modeling beam multifibrbe [R3.08.08]. The law of behavior of the concrete is Mazars in its version 1D [R7.01.08] for modeling A;
- the beam is represented by elements DKTG. The non-linear law of behavior used is GLRC_DM [R7.01.32] for modeling B.
1 General characteristics

1.1 Geometry

The geometry is identical to that of the CAS-tests SSNL119 and SDLL130 except for the longitudinal reinforcements which all are here identical: they are four HA32.

[NB: the transverse reinforcements are not taken into account in calculations.]

1.2 Material properties

For modeling a:

For the concrete, law of behavior of Mazars in its version 1D:

- Elasticity part:
  \[ E = 3.72720 \times 10^9 \text{ MPa} , \quad \nu = 0.2 , \quad \rho = 2.40 \times 10^3 \text{ kg/m}^3 \]

- Non-linear part:
  \[ AC = 1.71202987 \times 10^3 , \quad BC = 2.01163780 \times 10^3 , \quad BT = 1.21892353 \times 10^4 , \quad BETA = 1.10 , \quad AT = 1.00 , \quad EPSDO = 8.20396008 \times 10^{-5} \]

For modeling b:

- Béton:
  - Young modulus: \( E = 37272 \text{ MPa} \)
  - Poisson’s ratio: \( \nu = 0.2 \)
  - Threshold of elasticity in traction: \( \sigma_t = 3.9 \text{ MPa} \)
  - Threshold of elasticity in compression: \( \sigma_c = 38.3 \text{ MPa} \)

For modelings A and b:

- Law of behavior ECRO_LINE for steel:
  \[ E = 200000 \text{ MPa} , \quad \nu = 0.33 , \quad \sigma_e = 400 \text{ MPa} , \quad E_T = 3280 \text{ MPa} , \quad \rho = 7800 \text{ kg/m}^3 \]

-Damping: of Rayleigh type (\( \alpha K + \beta M \)), with 5% on modes 1 and 2.

Warning: The translation process used on this website is a "Machine Translation". It may be imprecise and inaccurate in whole or in part and is provided as a convenience.
1.3 Boundary conditions and loadings

Simple support in $B$ : $dy = 0$

Support “doubles” in $A$ : $dx = dy = 0$

To avoid the clean modes except plan, one blocks the following degrees of freedom on all the beam:

$r_x = r_y = dz = 0$

Loading: earthquake $\text{ac}_s2\_c_1$ [Figure 1.3-a], in the axis $OY$ applied to the two supports, with a factor of amplification of the signal of 45.

![Figure 1.3-a: hasccélérogramme ac_s2_c_1 imposed on the structure](image)

2 Reference solution

The tests carried out are only of standard not-regression.
3 Modeling A

3.1 Characteristics of modeling

Longitudinal grid of the beam:
It is composed of 17 nodes and 16 pairs of elements POU_D_EM (16 elements for the concrete and 16 for steel).

Cross section of the beam:
The concrete is modelled by a grid made up of $2 \times 20$ quadrilaterals (40 fibres).
Steel is modelled by 4 specific fibres.

Coefficients $\alpha$ and $\beta$ for damping are calculated using the following formula:

$$\begin{bmatrix} \alpha \\ \beta \end{bmatrix} = 2 \begin{bmatrix} \frac{1}{\omega_1 \omega_2} & -\frac{1}{\omega_2} \\ \frac{1}{\omega_2} & -\frac{1}{\omega_1} \end{bmatrix} \begin{bmatrix} \xi_1 \\ \xi_2 \end{bmatrix}$$

where $\omega_1$ and $\omega_2$ are the first two own pulsations ($\omega = 2\pi f$) and $\xi_1$ and $\xi_2$ are the depreciation wished on the first two modes.

With $f_1 = 39.9 \text{ Hz}$ and $f_2 = 157.6 \text{ Hz}$, we find: $\alpha = 8.10^{-5}$ and $\beta = 20$.

The step of selected time is $0.01 \text{ s}$.

The law for the behavior of the concrete is Mazars in its version 1D.

3.2 Sizes tested and results

The curves of reaction of support according to time as well as the arrow in the center according to time are presented on the figures 3.2-a with 3.2-b.
Figure 3.2-a : Réaction of support A according to time for the three first second.

Figure 3.2-b : Flick in the center according to time for the three first second.
The tests are carried out for the reaction on the first support and the arrow in the center. One tests these values for a few moments in the three first second of earthquake, i.e. at times 1.76s (any beginning of the nonlinear field), then 2.05s, 2.68s and 2.87s when the structure is already strongly damaged.

4 Modeling B

4.1 Characteristics of modeling

The beam is modelled by elements DKTG and GRILLE_EXCENTREE. One uses 16 elements in the longitudinal direction \( X \) and only one in the transverse direction \( Z \).

The reinforced concrete is modelled by the law of behavior GLRC_DM. Parameters of the law of behavior GLRC_DM are obtained thanks to the macro-order DEFI_GLRC. The data materials used are defined in 1.2. For the tablecloths of mainstays model GLRC, a section of reinforcement is defined

\[
OMX = OMY = 8.04E-4 \text{ m}^2/\text{m} \quad \text{and} \quad RX = RY = 0.872 .
\]

The option is used

\[
SLOPE \Leftarrow \_F ( \\
\quad \text{TRACTION} = \text{PLAS_ACIER}, \\
\quad \text{INFLECTION} = \text{UTIL}, \\
\quad \text{KAPPA_FLEX} = 3rd-3 , \\
\ ),
\]

The first two Eigen frequencies (calculated with Code_Aster) are \( f_1 = 38.7 \text{ Hz} \) and \( f_2 = 153.2 \text{ Hz} \). For modal depreciation of 5\%, one obtains the damping coefficients \( \alpha = 8.10^{-5} \) and \( \beta = 20 \). These coefficients are provided to the macro-order DEFI_GLRC.

4.2 Sizes tested and results

The curves of reaction according to time as well as the arrow in the center according to time are presented on the figures 4.2-a with 4.2-f.
