SZLZ106 - Tire under random request

Abstract:

The purpose of this test is computation of the damage from a random request which is characterized by its spectral moments.

From the spectral moments of the random loading one determines the average damage undergone by the structure [R7.04.02].

With this intention one has two methods of counting of cycles of stresses:

- method of counting of stresses peaks,
- method of the goings beyond a given level.

One tests also various possibilities of introduction the curve of Wöhler as well as the taking into account of the elastoplastic coefficient of concentration Ke .

The results of reference of this test are the values provided by software POSTDAM developed by Department REME (EDF-DER-EP).

Results provided by the operator POST_FATI_ALEA are completely identical to those provided by software POSTDAM.

1 Problem of reference

the analysis consists in determining the average damage undergone by a part subjected to a random loading.

Loading of the random type is entirely characterized by the values of the spectral moments of order 0,2 and 4: λ_0 , λ_2 and λ_4 which is introduced under key keys MOMENT_SPEC_0, MOMENT_SPEC_2 and MOMENT_SPEC_4.

For the computation of the damage it is necessary to choose a method of counting among the two available ones in *Code_Aster* :

- method of counting of stresses peaks,
- method of counting of going beyond a given level.

It is necessary moreover introduce the curve of Wöhler of the material which can be defined in three distinct mathematical forms:

- function point by point, which gives the value amongst cycles to the fracture, according to the alternating load S_{alt} ,
- analytical form of Basquin: $D = A\, S_{alt}^{\beta}$;
- analytical form "zones current"

S_{alt} = forced alternate = $1/2\,(E_C/E)\,\Delta\sigma$

$X = \log_{10}(S_{alt})$

$N = 10^{a0+a1\,X+a2\,X^2+a3\,X^3}$

$$D = \begin{cases} 1./N & \text{if } S_{alt} \geq S_l \\ 0. & \text{not} \end{cases}$$

where E_C = Young Modulus associated with the curve with fatigue with the material,

E = Young Modulus used to determine the stresses,

constants of the material $a0$ $a1$, $a2$ and $a3$,

and S_l limit of endurance of the material.

Moreover, one can possibly take account of a plastic coefficient of concentration élasto - Ke , defined by:

$$\begin{cases} K_e = 1 & si \quad \Delta\sigma < 3S_m \\ K_e = 1+(1-n)/(\Delta\sigma/3S_m-1)/(n(m-1)) & si \quad 3S_m < \Delta\sigma < 3mS_m \\ K_e = 1/n & si \quad 3mS_m < \Delta\sigma \end{cases}$$

where S_m is the acceptable maximum stress,

and n m two constants depending on the material.

In this test, for a single given random loading, one determines the average damage in ten distinct configurations, according to the shape of the curve of Wöhler and the method of counting of cycles.

1.1 Material properties for the study of fatigue

the properties of the material relate to the data of a curve of Wöhler making it possible to determine the number of cycles to the fracture for a level of loading given.

1.1.1 Curve of Wöhler in analytical form Basquin

Configuration 1

A	β
1.0017309939 E-14	4.065

Configuration 2

A	β
32. E-13	5.

1.1.2 Curve of Wöhler in form "zones current"

Parameters of definition of configuration 3:

$a0$	$a1$	$a2$	$a3$	Ec	E	Sl
11.495	– 5.	0.25	– 0.07	220000.	200000.	5.

Parameters of definition of configuration 4:

$a0$	$a1$	$a2$	$a3$	Ec	E	Sl
11.495	– 5.	0.25	– 0.07	220000.	200000.	5.

Moreover, one takes one account an elastoplastic coefficient of concentration Ke defined by the parameters for this configuration.

Sm	n	m
60.	0.6.1.4	

1.1.3 Curve of Wöhler in form function point by point (configuration 5)

S_{alt}	1.	2.5	.	25.	30.	35.	40.
