

ERREU05 - Checking of the recovery of the fatal errors in STAT_NON_LINE

Summary:

This test validates the recovery of the fatal errors in `STAT_NON_LINE` and the possibility of making a continuation starting from a base obtained at exit of a study having stopped in error.

1 Principle of the test

This test is a data-processing test. It is held in two phases:

- In a Premier time, the case test carries out a first `STAT_NON_LINE` during which an error occurs (problem of interpolation of a function). This error is intercepted and test bases it is correctly closed.
- In the second time, one `CONTINUATION` is carried out by using the base produced during the first calculation.
