

## WTNA112 – Thermal pressurization of a not drained saturated cylindrical test-tube

---

### Summary:

It is about a problem of THM saturated and elastic. One increases the temperature of a sample not drained maintained with constant containment (constant total constraint at the edge). The resulting water pressure varies then linearly with the temperature according to a thermal coefficient of pressurization which one calculates analytically. The solution obtained here is thus to compare with an analytical solution.

## 1 Problem of reference

### 1.1 Geometry

A cylinder of ray is considered  $1\text{ cm}$  and height  $1\text{ cm}$  (either a grid corresponding to a square field of  $1\text{ cm} \times 1\text{ cm}$ , modeling being axisymmetric).

### 1.2 Properties of material

One chooses parameters here corresponding to a mudstone so as to obtain a coefficient of realistic thermal pressurization.

Liquid water	Density ( $\text{kg.m}^{-3}$ )	$10^3$
	Specific heat with constant pressure ( $\text{J.K}^{-1}$ )	4180
	Dynamic viscosity of liquid water ( $\text{Pa.s}$ )	0.001
	Thermal dilation coefficient of the liquid ( $\text{K}^{-1}$ ) (so constant, cf following section)	$1.10^{-4}$
	Compressibility ( $\text{Pa}^{-1}$ )	$K_e = 5.10^{-10}$
Solid	Drained Young modulus $E(\text{Pa})$	$3,14 10^9$
	Poisson's ratio	0.375
	Thermal dilation coefficient of the solid ( $\text{K}^{-1}$ )	$10^{-5}$
State of reference	Porosity	0.18
	Temperature ( $\text{K}$ )	273
	Liquid pressure ( $\text{Pa}$ )	0
Homogenized coefficients	Homogenized density ( $\text{kg.m}^{-3}$ )	2410
	Coefficient of Biot	0.6
	Intrinsic permeability ( $\text{m}^2$ )	$K_{\text{int}} = 10^{-21}$
	Thermal conductivity	$\lambda_T = 1.61$

### 1.3 Boundary conditions and loadings

One imposes:

- On the low and left edges: worthless displacements, hydraulic flow no one, worthless heat fluxes. They are conditions of symmetry.
- On the edges high and right: Total constraint imposed on 12 MPa, hydraulic flow no one, imposed temperature function of time  $T(t)$  according to a linear slope such as:

$$T(t) = T_0 + \frac{\Delta T}{t_{sim}} \text{ where } t_{sim} \text{ corresponds at the time of simulation (here } t_{sim} = 1\text{h) and } \Delta T \text{ temperature variation imposed during this time (here } \Delta T = 40^\circ\text{C}).$$

## 1.4 Initial conditions

$$P(x) = 4\text{MPa and } T(x) = T_0 = 20^\circ\text{C everywhere.}$$

## 2 Reference solution

One recall that the contribution of water mass is written:  $m_w = \varphi \cdot \rho_w \cdot (1 + \varepsilon_v)$ , which one can derive in the following form:  $dm_w = d\varphi \rho_w (1 + \varepsilon_v) + d\rho_w \varphi (1 + \varepsilon_v) + \rho_w \varphi d\varepsilon_v$  with  $\varphi$  porosity eulérienne.

If one places oneself in assumption of small displacements, one will thus have:

$$dm_w = d\varphi \rho_w + d\rho_w \varphi + \rho_w \varphi d\varepsilon_v \quad (1)$$

The variation of porosity is written according to the relation:

$$d\varphi = (b - \varphi) \left( d\varepsilon_v - 3\alpha_0 dT + \frac{dp_w}{K_s} \right) \quad (2)$$

with  $\alpha_0$  the linear dilation of the skeleton (comparable to the porous environment). It is pointed out that the coefficient of Biot  $b$  and compressibility of the solid matter constituents modulates it  $K_s$  are connected to the "drained" module of compressibility of the porous environment  $K_0$ , such as:

$$b = 1 - \frac{K_0}{K_s}$$

In addition, the variation of the density of water is written:

$$\frac{d\rho_w}{\rho_w} = \frac{dp_w}{K_w} - 3\alpha_w dT \quad (3)$$

with the module of compressibility of water  $K_w$  and its module of dilation  $\alpha_w$ .

Lastly, if the law of behavior is elastic, it is pointed out that the deformation is connected to the effective constraint such as:

$$d\varepsilon_v = \frac{d\sigma'}{K_0} + 3\alpha_0 dT \quad (4)$$

In addition, the formulation in total constraint, indicates to us that:

$$d\sigma' = d\sigma + b dp_w, \text{ considering here that the mediums is with constant containment, one thus has:}$$

$d\sigma' = b dp_w$ , which gives us with the final one

$$d\varepsilon_v = \frac{b dp_w}{K_0} + 3\alpha_0 dT \quad (5)$$

One can now inject (2), (3), (4) and (5) in the equation (1) and one obtains that:

$$\frac{dm_w}{\rho_w} = \left( \frac{b^2}{K_0} + \frac{(b-\varphi)}{K_s} + \frac{\varphi}{K_w} \right) dp_w + \varphi (3\alpha_0 - 3\alpha_w) dT \quad (6)$$

Considering that the medium is not drained one thus has:

$$\left( \frac{b^2}{K_0} + \frac{(b-\varphi)}{K_s} + \frac{\varphi}{K_w} \right) dp_w = \varphi (3\alpha_w - 3\alpha_0) dT \quad (7)$$

What can be written in the form:

$$dp_w = \Lambda dT \quad (8)$$

With  $\Lambda$  the thermal coefficient of pressurization such as:

$$\Lambda = \frac{\varphi (3\alpha_w - 3\alpha_0)}{\left( \frac{b^2}{K_0} + \frac{(b-\varphi)}{K_s} + \frac{\varphi}{K_w} \right)}$$

It is noticed that this coefficient revealed the thermal differential  $(\alpha_w - \alpha_0)$

## 2.1 Thermal dilation of constant water

If  $\alpha_w = cte$  the digital application is immediate.

**Digital application:**

With the data defined previously, one obtains:

$$\Lambda = 2,25 10^5 Pa. K^{-1}$$

What gives for a temperature variation  $\Delta T = 40^\circ C$ , a variation of pressure of  $\Delta p = 9,01 Mpa$ .

## 2.2 Thermal dilation of water function of the temperature

In this case, one will write

$$\Lambda(T) = \frac{\varphi (3\alpha_w(T) - 3\alpha_0)}{\left( \frac{b^2}{K_0} + \frac{(b-\varphi)}{K_s} + \frac{\varphi}{K_w} \right)} \text{ and}$$

$$dp_w = \Lambda(T) dT$$

To be able to integrate this formula, it is considered that the thermal dilation of water is a linear function of the temperature such as  $\alpha_w = a.T + b$ .  $\Lambda(T)$  is then also a linear function which one integrates between the initial temperature  $T_0$  and final temperature  $T_1$ , which gives:

$$\Delta p = \frac{A}{2} \cdot (T2^2 - T1^2) + B(T2 - T1) \text{ with}$$

$$A = \frac{3 \phi a}{\left( \frac{b^2}{K_0} + \frac{(b-\phi)}{K_s} + \frac{\phi}{K_w} \right)}$$

and

$$B = \frac{\phi (3b - 3\alpha_0)}{\left( \frac{b^2}{K_0} + \frac{(b-\phi)}{K_s} + \frac{\phi}{K_w} \right)}$$

### Digital application:

One takes here

$a = 2,63 \cdot 10^{-6}$  and  $b = -7 \cdot 10^{-4}$  what corresponds to  $\alpha_w(293) = 6,67 \cdot 10^{-5} K^{-1}$  and  $\alpha_w(333) = 1,72 \cdot 10^{-4} K^{-1}$  and which constitutes realistic values for water.

Taking everything into account, one obtains for a temperature variation between 20°C and 60°C, a variation of pressure of  $\Delta p = 10,9 MPa$  and thus a final pressure of 14,9 MPa .

## 3 Modeling A

---

### 3.1 Characteristics of modeling A

- Plane modeling 'AXIS\_THMS'. Mechanical law 'ELAS'. Coupling 'LIQU\_SATU'.
- $20 \times 20$  elements  $Q4$  of equal width.
- Thermal dilation of constant water

### 3.2 Results of modeling A

Discretization in time: 10 pas de time of 180 s each one. The solution calculated by Aster which takes account of the movements of the fluid and heat (diffusive phenomena), it is normal not to obtain the reference solution exactly. The differences remain very weak.

Result at the final moment 3600 s :

$N^\circ$ NODE	COOR_X	COOR_Y	Reference PREI (MPa)	Aster PREI (MPa)	Differences (%)	Tolerance (%)
1	0	0	13,01	12,98	0,158	1
2	0	0.01	13,01	12,99	0,098	1

## 4 Modeling B

### 4.1 Characteristics of modeling B

- Plane modeling 'AXIS\_THMS'. Mechanical law 'ELAS\_ORTH'. Coupling 'LIQU\_SATU'.  
20x20 elements Q4 of equal width. Also anisotropic terms of couplings.

It acts of the same modeling as previously but via the modules of orthotropism (although the test-tube is regarded as isotropic and that the characteristics remain the same ones in each direction). In theory the results should give the same thing exactly.

The model differs however here slightly and the analytical solution indicated previously is not completely any more exact. Indeed instead of the relation used into isotropic:

$$d\varphi = (b - \varphi) \left( d\varepsilon_V - 3\alpha_0 dT + \frac{dp_w}{K_s} \right)$$

The relation used in this case becomes tensorial (cf Doc. R7.01.11) and is:

$$d\varphi = \mathbf{B} : d\varepsilon - \varphi d\varepsilon_V - 3\alpha_\varphi dT + \frac{dp_{gz} - S_{lg} dp_c}{M_\varphi}$$

with

$$\frac{1}{M_\varphi} = (\mathbf{B} - \varphi \delta) : \mathbf{S}_0^S : \delta$$

where  $\mathbf{S}_0^S$  the matrix of flexibility of the skeleton, function of the Young modulus of the solid matrix  $E^S$  and of the Poisson's ratio of the solid matrix  $\nu^S$ .

In addition porosity cannot be integrated here analytically and is thus in an explicit way (porosity taken at previous time). The resolution is thus here less precise.

This modeling aims to quantify the difference obtained via this modeling.

### 4.2 Results of modeling B

One tests the same results as previously initially on 10 pas de time as for modeling A

**Result at the final moment 3600 s :**

N° NODE	COOR_X	COOR_Y	Reference PREI (MPa)	Aster PREI (MPa)	Differences (%)	Tolerance (%)
1	0	0	13,01	12,258	3,25	5
2	0	0.01	13,01	12,259	2,80	5

The results got here are a little less precise than previously what is explained by the explicit treatment of porosity.

To ensure itself some one tests the same case but with 15 pas de time:

**Result at the final moment 3600 s :**

N° NODE	COOR_X	COOR_Y	Reference PREI (MPa)	Aster PREI (MPa)	Differences (%)	Tolerance (%)
1	0	0	13,01	12.994	0,04	1
2	0	0.01	13,01	13.001	0,01	1

One converges perfectly towards the analytical solution.

## 5 Modeling C

---

### 5.1 Characteristics of modeling C

- Plane modeling 'AXIS\_THMS'. Mechanical law 'ELAS'. Coupling 'LIQU\_SATU'.
- 2 triangular elements
- Thermal dilation of water according to a linear law (cf section 2.2)

### 5.2 Results of modeling C

Discretization in time: 30 pas de time of 120 s each one. The solution calculated by Aster which takes account of the movements of the fluid and heat (diffusive phenomena), it is normal not to obtain the reference solution exactly. The differences remain very weak.

Result at the final moment 3600 s :

$N^{\circ}$ NODE	COOR_X	COOR_Y	Reference PREI (MPa)	Aster PREI (MPa)	Differences (%)	Tolerance (%)
4	0	0	14,9	14,84	0,7	1
1	0	0.01	14,9	14,84	0,7	1

## 6 Summary of the results

---

The results are in coherence with the analytical solution.
